- 4 Future work

Motivations

Plan

- 1 Motivations
- 2 Background
- 3 Results
- 4 Future work

■ An example :

Credits: Sylvain Calinon

Motivations

- ▶ How to take the teacher's demonstration into account?
 - Exactly reproduce the teacher's actions
 - Use demonstration data to build a representation of the environment's dynamics
 - ▶ Use the teacher's demonstration as an exploration baseline

- Child learning to dance: first follows its teacher's moves, before trying out new ones once he feels he has exploited the teacher's recommandations.
 - ⇒ notion of compliance w.r.t the teacher.

Motivations

■ Goal :

- Introduce a theoretical framework for compliance-based learning
- Grasp ideas and intuitions about how such an approach can
 - Overcome a mentor's (large) sub-optimality.
 - Speed up the learning
 - Generalize to transfer learning

in a reinforcement learning framework.

Method:

- Create a simple but generic Markov Decision Process
- Solve it using classical RL method
- Implement compliant-based learning methods

Plan

- 4 Future work

■ RL :

- Framework in which an agent (or a learner) learns its actions from interacting with its environment
- ► The environment generates scalar values called rewards, that the agent is seeking to maximize over time.

Under a Markovian asumption, formulated as a Markov Decision Process:

$$(\mathcal{S}, \mathcal{A}(\mathcal{S}), \mathcal{P}_{ss'}^{a}, \mathcal{R}_{ss'}^{a}) \tag{1}$$

where:

$$\mathcal{P}_{ss'}^{a} = \underbrace{\mathbb{P}(s_{t+1} = s' \mid s_{t} = s, \ a_{t} = a)}_{dynamics} \qquad \mathcal{S} : \text{ state space}$$

$$\mathcal{R}_{ss'}^{a} = \underbrace{\mathbb{E}\left[r_{t} \mid s_{t+1} = s', \ s_{t} = s, \ a_{t} = a\right]}_{immediate reward} \qquad \mathcal{A}(\mathcal{S}) : \text{ action space}$$

$$(2)$$

■ RL :

▶ Define state value and action value functions under a policy (probabilistic decision rule) $\pi: \mathcal{S} \to \mathcal{A}$:

$$V^{\pi}(s) = \mathbb{E}_{\pi} \left[\sum_{i} \gamma^{i} r_{t+i+1} | s_{t} = s \right]$$

$$Q^{\pi}(s, a) = \mathbb{E}_{\pi} \left[\sum_{i} \gamma^{i} r_{t+i+1} | s_{t} = s, a_{t} = a \right]$$
(3)

- Algorithms computing optimal policies rely on various mix of a Generalized Policy Iteration¹:
 - 1. Evaluate the current policy (DP,..)
 - 2. Improve the current policy (greedization)
 - 3. Repeat

¹Richard S. Sutton and Andrew G. Barto. *Reinforcement Learning: An Introduction*.

■ Solving RL : Two baseline methods :

- ▶ Model-based ($\mathcal{P}_{ss'}^a$ and $\mathcal{R}_{ss'}^a$ are known) : dynamic programming (value iteration algorithm, ...)
- ► Model-free : exploitation vs exploration paradigm for computing the optimal policy's Q-values :

$$\{Q(s,a)\}_{s\in\mathcal{S},a\in\mathcal{A}(s)}\tag{4}$$

- ► Bootstrap from initial value
- Update in direction of the sampled expected return

$$Q(s, a) \leftarrow (1 - \alpha)Q(s, a) + \alpha \mathbb{E}\left[R_t|s, a\right]$$
 (5)

 Many different variations : SARSA, Q-learning, R-learning, eligibiliy traces....

■ Imitation learning :

- ► For long and complex tasks : common machine learning algorithms are usually very slow to converge
- ► Accelerate learning via prior knowledge of the environment or task : provide a demonstration of the task
- ► Framework of *learning from demonstration* (LfD)²

 \longrightarrow Ex. : robotic arm grabbing a cup

: maze solver

- Transfer learning: speeding a learning process thanks to another learning experience.
 - ▶ Provide the learner with a mentor that is another learner
 - ► In homogeneous settings³
 - Study how convergence is affected

and eventually generalize to

- multiple teachers
- inhomogeneous settings

Results

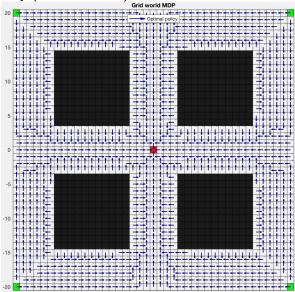

Plan

- 1 Motivations
- 2 Background
- 3 Results
 - Markov Decision Process
 - Compliance-based learning
 - Method comparaison
- 4 Future work

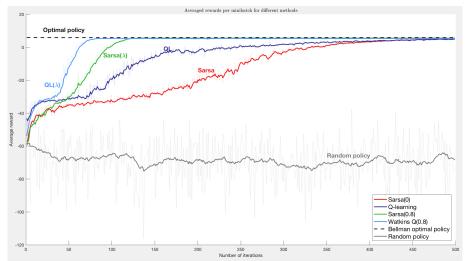

■ Generic and simple state space :

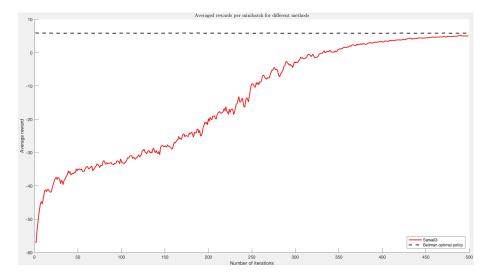

■ Optimal Policy (value iteration) :

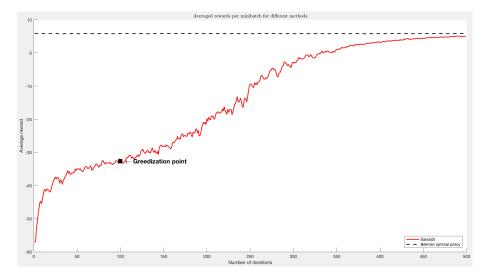

■ Learning the optimal policy

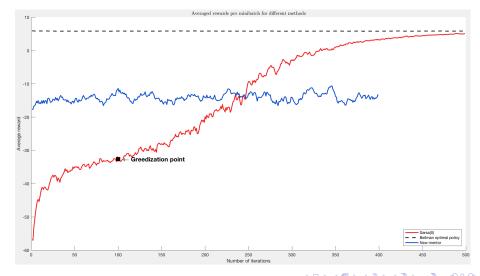

■ Generating a suboptimal mentor

■ Generating a suboptimal mentor

■ Generating a suboptimal mentor

- Compliance learning
- → Intuitively :
 - Follow the teacher
 - ▶ Gain some knowledge about the environment and the task
 - ► Take our own actions
- → The teacher should only influence our action selection:
 - ▶ Global compliance term : $p \in [0, 1]$
 - ▶ p-greedy action selection w.r.t the mentor's action a_m : $\forall s \in \mathcal{S}$

$$\pi(s) = \begin{cases} a_m \text{ with probability } p \\ a \in \mathcal{A}(s) \text{ (Gibbs softmax)} \end{cases}$$
 (6)

■ Vanishing compliance :

► Constantly decreasing compliance :

$$\begin{vmatrix} p_0 \in [0,1] \\ p_{t+1} = \beta p_t, \quad \beta < 1 \end{vmatrix}$$

$$(7)$$

Along with SARSA update :

$$Q(s,a) \leftarrow Q(s,a) + \alpha(r + \gamma Q(s',a') - Q(s,a))$$
 (8)

ightharpoonup Start with $p_0 \simeq 1$ (high confidence) and slowly decide to take your own decisions.

■ Constantly decreasing compliance :

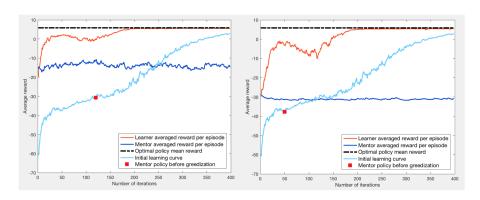

Figure: Average reward for two naive compliance learners

■ Learning the compliance term

 $\forall s \in \mathcal{S}$, define p(s) - compliance term that impact the action selection :

$$\pi(s) = \begin{cases} a_m \text{ with probability } p(s) \\ a \in \mathcal{A}(s) \setminus a_m \text{ with probabiliy } 1\text{-p(s)} \end{cases}$$
 (9)

Goal: learn p(s), $\forall s \in S \rightarrow$ measure how right the teacher seems to be

▶ Implicit β -compliance :

▶ $\forall s \in \mathcal{S}$, provide p(s) with a Beta prior $(\alpha >> \beta)$

$$p(s) \sim B(\alpha(s), \beta(s))$$
 (10)

▶ Given a (s,a,r,s',a') 5-tuple, compute the critic TD value :

$$\delta_t = r + \gamma Q(s', a') - Q(s, a_m) \rightarrow \text{how good is the teacher ?}$$
 (11)

▶ Compute **posterior distribution** over p(s):

$$\alpha_t(s) \leftarrow \alpha_t(s) + \mathbb{1}_{a=a_m} \delta_t \varepsilon_t \beta_t(s) \leftarrow \beta_t(s) + \mathbb{1}_{a \neq a_m} \delta_t \varepsilon_t$$
(12)

▶ Implicit β -compliance :

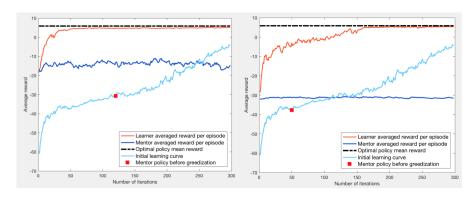

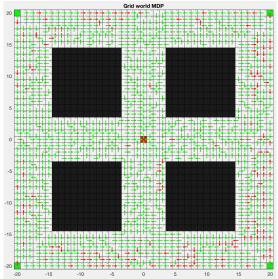

Figure: Average reward for two actor-critic compliance learners

- ► Faster convergence
- ▶ No undershoot + tuning is intuitive

▶ Implicit β -compliance :

Explicit compliance :

Adds a hierarchical MDP :

$$\forall s \in \mathcal{S}, \, \mathcal{A}_c(s) = \{' \textit{listen}', \, '\textit{discard}' \}$$
 (13)

▶ Define exploration based on $\{Q_c(s, l), Q_c(s, d)\}$:

$$\forall s \in \mathcal{S}, \quad \pi_c(s) = \begin{cases} 'l' \text{ with probability } p(s) = \sigma \left(\frac{Q_c(s, l) - Q_c(s, d)}{\tau} \right) \\ 'd' \text{ with probability } 1 - p(s) \end{cases}$$
(14)

- Perform SARSA update
- Update :

$$\begin{cases}
Q_c(s,l) \leftarrow \beta Q_c(s,l) + (1-\beta)Q(s,a_m) \\
Q_c(s,d) = \beta Q_c(s,d) + (1-\beta) \max_{a \neq a_m} Q(s,a)
\end{cases}$$
(15)

► Explicit compliance :

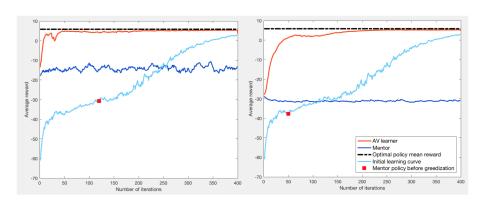

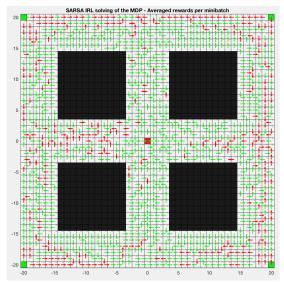

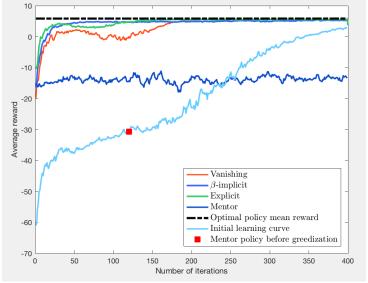

Figure: Average reward for two action-value compliance learners

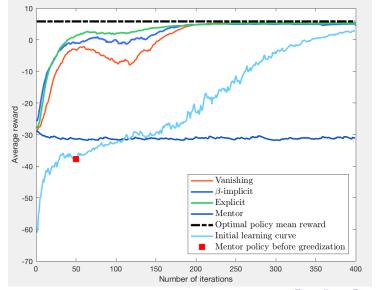

► Explicit compliance :

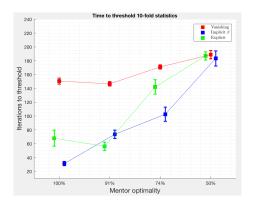

▶ Method comparaison : learning curves

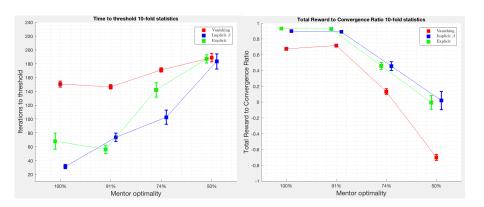

Method comparaison: learning curves

▶ Method comparaison : f-fold metrics statistics

▶ Method comparaison : f-fold metrics statistics

Future work

Plan

- 1 Motivations
- 2 Background
- 3 Results
- 4 Future work

Future work

► Future Work

- Convergence and final result is too much impacted by the mentor : off-policy generalization
- Eligibility-trace formulation
- ► Generalize to several mentors
- ► Generalize to sparse recommandations

Thank you for your attention!
